

# Chatbot vs AI Agent

- Both of them use LLM to communicate with user.
- Main different are
  - **autonomy**
  - **reasoning**
  - **the ability to take action.**

| Feature          | The Chatbot (Chatbot)                                                         | The AI Agent                                                                                                                        |
|------------------|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Primary Function | Conversational response generation.                                           | Goal-oriented problem solving.                                                                                                      |
| Workflow         | <b>Reactive:</b> User asks a question → LLM generates text → User reads text. | <b>Proactive:</b> User gives a goal → Agent plans steps → Agent uses tools → Agent evaluates results → Agent delivers final answer. |
| Tool Usage       | None. Relies entirely on the data it was trained on.                          | Extensive. Can access APIs, search the web, query databases, or run code.                                                           |
| Reasoning        | Single-step. It predicts the next best word based on the prompt.              | Multi-step. Uses frameworks like <u>ReAct</u> (Reason + Act) to think through a problem before acting.                              |

Chatbot is without tool calling. It generate only using his knowledge

Agent use tool call and call to the most needed one. because of that it become rational.
